

# Asynchronous Pi Calculus

Thursday, September 29, 2011  
13:27

$$\begin{aligned}
 P &::= M \mid P_1 \mid P_2 \mid \nu x P \mid !P \\
 M &::= 0 \mid \pi.P \mid M_1 + M_2 \\
 \pi &::= \tau \mid \bar{x}(y) \mid x(y) \mid [x=y] \pi
 \end{aligned}
 \left. \vphantom{\begin{aligned} P \\ M \\ \pi \end{aligned}} \right\} \begin{array}{l} \text{full } \pi \text{ calculus} \\ \rightarrow \text{synchronization} \\ \text{occurs on guards.} \end{array}$$

## Asynchronous Pi Calculus

- meant to more accurately model real systems with finite buffers, different delays, reordering, lossy channels
- turns out there's an asynchronous fragment of  $\pi$ -calculus

→ we must re-build the guard idea to allow asynchronous operation

→ one way to do this is to not allow sends to guard processes.

$$\begin{aligned}
 P &::= \bar{x}(y) \mid M \mid P_1 \mid P_2 \mid \nu x P \mid !P \\
 M &::= 0 \mid x(y).P \mid \tau.P \mid M_1 + M_2
 \end{aligned}$$

★ think about sends being already happened, or just being guarded by  $\tau$ 's. This way it can happen at any time, so we need to be delay insensitive

$$\begin{aligned}
 \bar{x}(y) + w(z).P & \\
 \bar{x}(y) + \bar{x}(z) & \left\{ \begin{array}{l} \text{one could} \\ \text{model loss like this,} \\ \text{or, explicitly:} \end{array} \right.
 \end{aligned}$$

$$!x(y).0 \Rightarrow \text{!dev/null}$$

$$\bar{x}(y) \mid x(z).P + M \rightarrow P \{y/z\}$$

How do we enforce some sort of ordering:

$$\nu y, z (\bar{x}(y) \mid \bar{y}(z) \mid \bar{z}(a) \mid R) \text{ where } y, z \notin \text{fv}(R)$$

this enforces ordering, assuming  $\mathbb{R}$  has all the appropriate receivers.

More complicated example:

$$v_{x,w,u} (\bar{x} \langle w \rangle \mid w(u) \cdot (\bar{u} \langle u \rangle \mid w(z) \cdot \bar{z} \langle b \rangle)) \mid$$

$$\left( x(w) \cdot \left( (\bar{w} \langle u \rangle \mid u(y) \cdot v_z (\bar{w} \langle z \rangle \mid z(b)) \cdot Q \{ \{ \{ \} \} \} \right) \right)$$

these banana brackets mean "translation", many weird brackets

$\llbracket \cdot \rrbracket$ : Full  $\pi$  calculus into Async  $\pi$  calculus

$(\cdot)$

$\llbracket \cdot \rrbracket$

$\{\{ \cdot \}\}$

$$\llbracket \bar{x} \langle y \rangle \cdot P \rrbracket \cong v_w (\bar{x} w \mid w(u) \cdot (\bar{u} \langle y \rangle \mid \llbracket P \rrbracket))$$

$$\llbracket x(z) \cdot Q \rrbracket \cong x(w) \cdot v_u (\bar{w} \langle u \rangle \mid u(z) \cdot \llbracket Q \rrbracket)$$

full  $\pi$  calculus  $\rightarrow$  Async  $\pi$  calculus

$$P ::= \bar{x} \langle y \rangle \mid \sum_i x_i(z) \cdot P_i \mid P_1 \mid P_2 \mid v_z P \mid !P$$

$\uparrow$

we'd like to express this with primitives.

$\rightarrow$  we can do so w/ parallel composition

and lots of channel communication

$\rightarrow$  we can actually "get rid of" summation

$\pi$  calculus, because we can build up

to it w/ primitives  $\rightarrow$  we still need  $0$   $\gamma$  and  $\text{!ary sum}$

$\rightarrow$  we'll also lose  $\bar{\cdot}$ -transitions as well

$M \rightarrow M + N$

$(\cdot)$  - homo morphic except for one case

In [abstract algebra](#), a **homomorphism** is a structure-preserving [map](#) between two [algebraic structures](#) (such as [groups](#), [rings](#), or [vector spaces](#)). The word *homomorphism* comes from the [Greek language](#): [ὁμός](#) (*homos*) meaning "same" and [μορφή](#) (*morphe*) meaning "shape".

Pasted from <http://en.wikipedia.org/wiki/Homomorphism>

### Definition

The definition of homomorphism depends on the type of [algebraic structure](#) under consideration. Particular definitions of homomorphism include the following:

- A group homomorphism is a homomorphism between two groups.
- A ring homomorphism is a homomorphism between two rings.
- A linear map is a homomorphism between two vector spaces.
- An algebra homomorphism is a homomorphism between two algebras.
- A functor is a homomorphism between two categories.

The common theme is that a homomorphism is a function between two algebraic objects that respects the algebraic structure.

For example, a group is an algebraic object consisting of a set together with a single binary operation, satisfying certain axioms. If  $G$  and  $H$  are groups, a **homomorphism** from  $G$  to  $H$  is a function  $f: G \rightarrow H$  such that

$$f(g_1 * g_2) = f(g_1) *' f(g_2)$$

for any elements  $g_1, g_2 \in G$ , where  $*$  denotes the operation in  $G$  and  $*'$  denotes the operation in  $H$ .

When an algebraic structure includes more than one operation, homomorphisms are required to preserve each operation. For example, a ring possesses both addition and multiplication, and a homomorphism between two rings is a function such that

$$f(r + s) = f(r) +' f(s) \quad \text{and} \quad f(r * s) = f(r) *' f(s)$$

for any elements  $r$  and  $s$  of the domain ring.

The notion of a homomorphism can be given a formal definition in the context of universal algebra, a field which studies ideas common to all algebraic structures. In this setting, a homomorphism  $f: A \rightarrow B$  is a function between two algebraic structures of the same type such that

$$f(\mu_A(a_1, \dots, a_n)) = \mu_B(f(a_1), \dots, f(a_n))$$

for each  $n$ -ary operation  $\mu$  and for all elements  $a_1, \dots, a_n \in A$ .

Pasted from <<http://en.wikipedia.org/wiki/Homomorphism>>

only valid for summation of recurs.

Does not support  $\sum \bar{x}_i(z) \cdot P_i$

parallel composition  $\rightarrow \prod_i x_i(z) \cdot v_{p,f}(\bar{l} \langle p, f \rangle \mid p \cdot (\text{Fail} \langle l \rangle \mid (P_i)))$

operator  $\prod_{i=0}^N P_i = P_0 \mid P_1 \mid \dots \mid P_N$

Proceed( $l$ )  $\hat{=} l \langle p, f \rangle \cdot \bar{p}$

Fail( $l$ )  $\hat{=} l \langle p, f \rangle \cdot \bar{f}$

Annotations: ① everyone receives, ② all lock here someone wins, ③ winner gets to proceed, ④ winner sets up for others to fail, ⑤ winner does its  $P_i$ , ④ fails fail, ⑤ rebuild sum, ⑤ this sits around w/ no-one to interact w/ other

Now we will extend the encoding:

$$P ::= \bar{x} \langle y \rangle \mid M \mid P_1 \mid P_2 \mid v \in P \mid ! P \mid \omega$$

$$M ::= \sum_i x_i(z) \cdot P_i$$

$$N ::= \sum_i \bar{x}_i(d_i) \cdot P_i$$

we just built this w/  $(=)$  iff we only support summations of receives. if we also support

summations of receiver. if we also support summations of sends, the (i) definition is bogus

Ok, let's build this monstrosity to support sums of receivers AND sends

"easy" case first:

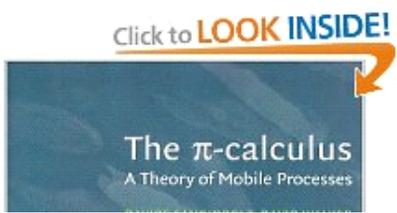

$$\{\sum_i x_i \langle d_i \rangle . P_i\} \triangleq v s (\text{Proceed} \langle s \rangle \mid \prod_i v a \ x_i \langle d_i, s, a \rangle \cdot v p, f (\bar{a} \langle p, f \rangle \mid p. \{\{P_i\}\} \mid f. 0))$$

$$\{\sum_i y_i \langle d_i \rangle . Q_i\} \triangleq v r (\text{Proceed} \langle r \rangle \mid \prod_i v g \ (g \mid g \cdot y_i \langle z, s, a \rangle \cdot v p_1, f_1 (\bar{r} \langle p_1, f_1 \rangle \mid p_1 (v p_2, f_2 (\bar{s} \langle p_2, f_2 \rangle \mid p_2 (\text{Fail} \langle r \rangle \mid \text{Fail} \langle d_i \rangle \mid \text{Proceed} \langle a \rangle \mid \{\{Q_i\}\})) \mid f_2 (\text{Proceed} \langle r \rangle \mid \text{Fail} \langle r \rangle \mid \text{Fail} \langle a \rangle \mid g \bar{y}))) \mid f_1 (\text{Fail} \langle r \rangle \mid g \bar{y}_i \langle z, s, a \rangle)))$$

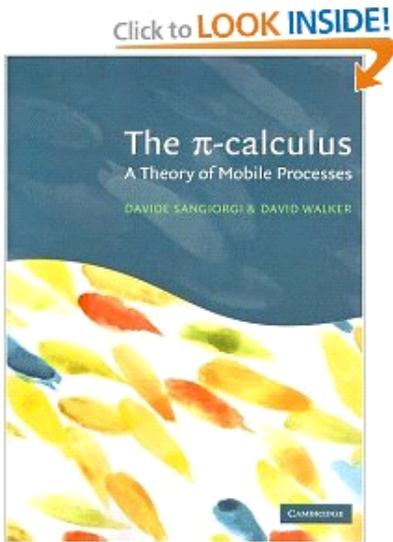

this is super complicated. all it does is choose one receiver to continue, and set up all the other ones to try again next "cycle"
